Block code - Wikipedia

For the general case of linear block codes, all the n digits of X are formed by linear combinations (modulo-2 additions) of k message bits. A special case, where $x_0 = m_0, x_1 = m_1, x_2 = m_2 \dots x_{k-1} = m_{k-1}$ and the remaining digits from x_{k+1} to x_n are linear combinations of $m_0, m_1, m_2,$

6.1 Encoding Linear Block Codes Recall that a linear block code takes k -bit message blocks and converts each such block into n -bit coded blocks. The rate of the code is k/n . The conversion in a linear block code involves only linear operations over the message bits to produce codewords. For concrete-ness,

partitioned into block codes and convolutional codes, although turbo codes can be seen as a hybrid of these two types. Linear codes allow for more efficient encoding and decoding algorithms than other codes (cf. syndrome decoding).

Linear block coders are a group of block coders that follow a special set of rules when choosing which set of outputs to use. The rules are as follows, using a (6,3) code for illustrative purposes: Let V_n = the set of all possible 64 6-bit sequences. U = the set of eight 6-bit sequences output at the channel coder. Using this notation, the rule
